

Empagliflozin to reduce the combined relative risk of cardiovascular complications

03 September 2020 | Analysis | By Hithaishi CB

Empagliflozin reduces the cardiovascular death and hospitalization for heart failure by 25 percent in adults with and without diabetes who had heart failure with a reduced ejection fraction

Full results from the EMPEROR-Reduced Phase III trial in adults with heart failure with reduced ejection fraction, with and without diabetes, showed that empagliflozin was associated with a significant 25 percent relative risk reduction in the primary endpoint of time to cardiovascular death or hospitalization due to heart failure. The trial evaluated the effect of adding empagliflozin (10 mg) versus placebo to standard of care. The results were presented at the ESC Congress 2020, the annual meeting of the European Society of Cardiology, and published in *The New England Journal of Medicine*, Boehringer Ingelheim and Eli Lilly and Company announced.

The findings from the primary endpoint were consistent in subgroups with and without type 2 diabetes. Key secondary endpoint analyses from the trial demonstrated that empagliflozin reduced the relative risk of first and recurrent hospitalization for heart failure by 30 percent. Additionally, the rate of decline in eGFR, a measure of kidney function decline, was slower with empagliflozin than with placebo.

"Heart failure is a devastating and debilitating cardiovascular condition. Not only does it limit quality of life, but it is also a progressive disease that requires repeated hospitalizations and is accompanied by a loss in kidney function," said Milton Packer, M.D., Chair of the Executive Committee for the EMPEROR Program and Distinguished Scholar in Cardiovascular Science at Baylor University Medical Center in Dallas, Texas, U.S.. "Results from the EMPEROR-Reduced trial show that, when given to adults with heart failure with reduced ejection fraction, empagliflozin reduces the number of heart failure hospitalizations while slowing the decline of kidney function. We hope that these findings will improve outcomes for people living with heart failure worldwide."

In an exploratory analysis, the absolute risk reduction observed in the primary endpoint of

EMPEROR-Reduced corresponded to a number needed to treat of 19 patients over 16 months to prevent one cardiovascular death or hospitalization for heart failure. An additional exploratory analysis showed that empagliflozin decreased the relative risk of a composite kidney endpoint*, including end stage kidney disease or a profound loss of kidney function, by 50 percent.

In EMPEROR-Reduced, the efficacy results were achieved with a simple dosing regimen, with once daily dosing and no need for titration. The safety profile was similar to the well-established safety profile of empagliflozin. There were no clinically meaningful differences in adverse events including hypovolemia (decreased blood volume), hypotension (low blood pressure), volume depletion (loss of fluids), renal insufficiency (poor kidney function), hyperkalemia (high potassium levels) or hypoglycemic events (low blood sugar) compared with placebo.

Heart failure affects over 60 million people worldwide, with more than one million people being hospitalized due to the condition every year in the U.S. and Europe. Closer to home, 4.5% of Singaporeans live with heart failure, compared to 1%–2% of the population in the US and Europe. In fact, the age-adjusted heart failure hospital admission rate in Singapore rose by approximately 40% in the last decade, making the condition the most common cardiac-cause of hospitalization. The 5-year survival rate in patients with heart failure is only at 32% in Singapore.

“Not only is the rising heart failure-related hospital admission rate in Singapore concerning, but some patients are also being readmitted soon after being released while others may not survive the condition. This indicates a need for treatment options that will improve outcomes for people living with heart failure. With the positive results from the EMPEROR-R trial, we are excited to provide data that will lead to a major step forward on how patients with heart failure can be treated in Singapore and around the world” said Professor Dr Joerg Kreuzer, Regional Medical Director, Boehringer Ingelheim (South East Asia & South Korea).

Heart failure occurs when the heart cannot pump sufficient blood to the rest of the body and is the most common and severe complication of a heart attack. People with heart failure often experience breathlessness and fatigue, which can severely impact their quality of life. Individuals with heart failure often also have impaired kidney function, which can have a significant negative impact on prognosis.

“Heart failure can have a profound impact on people living with the condition, with the potential of life limiting consequences for the heart and the kidneys,” said Waheed Jamal, M.D., Corporate Vice President and Head of CardioMetabolic Medicine, Boehringer Ingelheim. “Empagliflozin was the first SGLT2 inhibitor to demonstrate a reduction in cardiovascular death and hospitalization due to heart failure in people with type 2 diabetes and established cardiovascular disease, based on the EMPA-REG OUTCOME[®] trial. We continue to break new ground with the EMPEROR-Reduced results, which provide robust evidence that empagliflozin can transform the lives of millions of people through reducing cardiovascular outcomes and slowing the progression of kidney damage in people with heart failure. We look forward to exploring these data further and are planning regulatory submissions for later this year.”

“Tens of millions of people live with heart failure and kidney disease, including many who also have diabetes,” said Jeff Emmick, M.D., Ph.D., Vice President, Product Development, Lilly. “Results from EMPEROR-Reduced show that empagliflozin can help improve heart failure outcomes while also slowing kidney function decline. We are excited to share these data and, through our ongoing EMPOWER program, hope to redefine how people living with these conditions are treated.”

The U.S. Food and Drug Administration (FDA) has granted Fast Track designation to empagliflozin for the reduction of the risk of cardiovascular death and hospitalization for heart failure in people with heart failure. This designation is for the EMPEROR program, which consists of the EMPEROR-Reduced and EMPEROR-Preserved trials. EMPEROR-Preserved is exploring the effect of empagliflozin on cardiovascular death or hospitalization for heart failure in adults with heart failure with preserved ejection fraction, an area that currently has no approved treatment options. EMPEROR-Preserved results are expected in 2021.

Additionally, the ongoing EMPA-KIDNEY study is evaluating the effect of empagliflozin on the progression of kidney disease and occurrence of cardiovascular death in adults with established chronic kidney disease, with and without diabetes. The FDA has also granted Fast Track designation to empagliflozin for the treatment of chronic kidney disease, demonstrating the urgent need for new treatment options for people living with the condition worldwide. Results from EMPA-KIDNEY are expected in 2022.

The EMPEROR and EMPA-KIDNEY studies are part of the EMPOWER clinical program, the broadest and most comprehensive of any SGLT2 inhibitor, exploring the impact of empagliflozin on the lives of people across the spectrum of cardio-renal-metabolic conditions. The program also includes the EMPACT-MI study, which will investigate the effect of empagliflozin on allcause mortality and hospitalization for heart failure in adults, with and without diabetes, who have had a

heart attack, and the EMPULSE study, which is exploring empagliflozin in adults, with and without diabetes, who are hospitalized for acute heart failure and have been stabilized.
